

## **A Cure for Cancer?**

### *Using the Patient's Own Immune System To Fight Cancer?*

### **Research Question**

My *hypothesis* is this:

You can battle cancer by taking some blood out of the patient, isolating the T-cells, multiplying them outside of the human body, and injecting them into the cancerous growth.

Some patients that are aware of the fact that they have a cancerous growth somehow manage to channel the focus of their immune system on the cancerous growth. They are sufficiently interlinked to fight problems in their body through their own volition. It has been shown more than once that some cancer patients cured themselves.

Most patients aren't like that. What if we can help these patients and their immune systems by isolating their own natural defenses, harnessing them and reintroducing them into their bodies where needed as described? What would this do?

If it does work on single cancerous growths that is sufficient to deem the experiment successful. Nominal keeps the patients alive and gets them back to good health. It might take a considerable amount of injections, but that greatly outweighs the cost of having many tiny puncture wounds.

The optimal result would be that the onslaught of the T-cells on the cancerous growth leads to lots of waste to be produced that the immune system picks up on. If the immune system picks up on the residu produced by breaking down the cancer cells, it might now of its own natural volition produce more T-cells, since it gets the body is sick.

Either way it's a good idea to harness the body's own strengths and use them to enforce the immune system. If it's possible to cure cancer in this way, you don't need chemo-therapy or radiation, meaning that patients don't get sick more before they get healthy, greatly improving the odds of their survival.

If this works, for the "economists" out there, it's also cheap, as in a major budget cut. The hospitals can do this themselves, even now, with the means they already have at their disposal.
